Objectives

- ▶ Utilize frequent sounding and surface data to analyze the evolution of atmospheric stability over Taiwan for synoptic and non-synoptic events during TiMREX and resulting convection.
- ▶ Compare CAPE/CIN fields derived from observations with NWP models and VDRAS retrieved estimates.
- ▶ Evaluate the contribution of the gridded fields to short term nowcasting, particularly in monitoring and automatically tracking with time the changes in stability occurring prior to storm initiation and to storm dissipation.

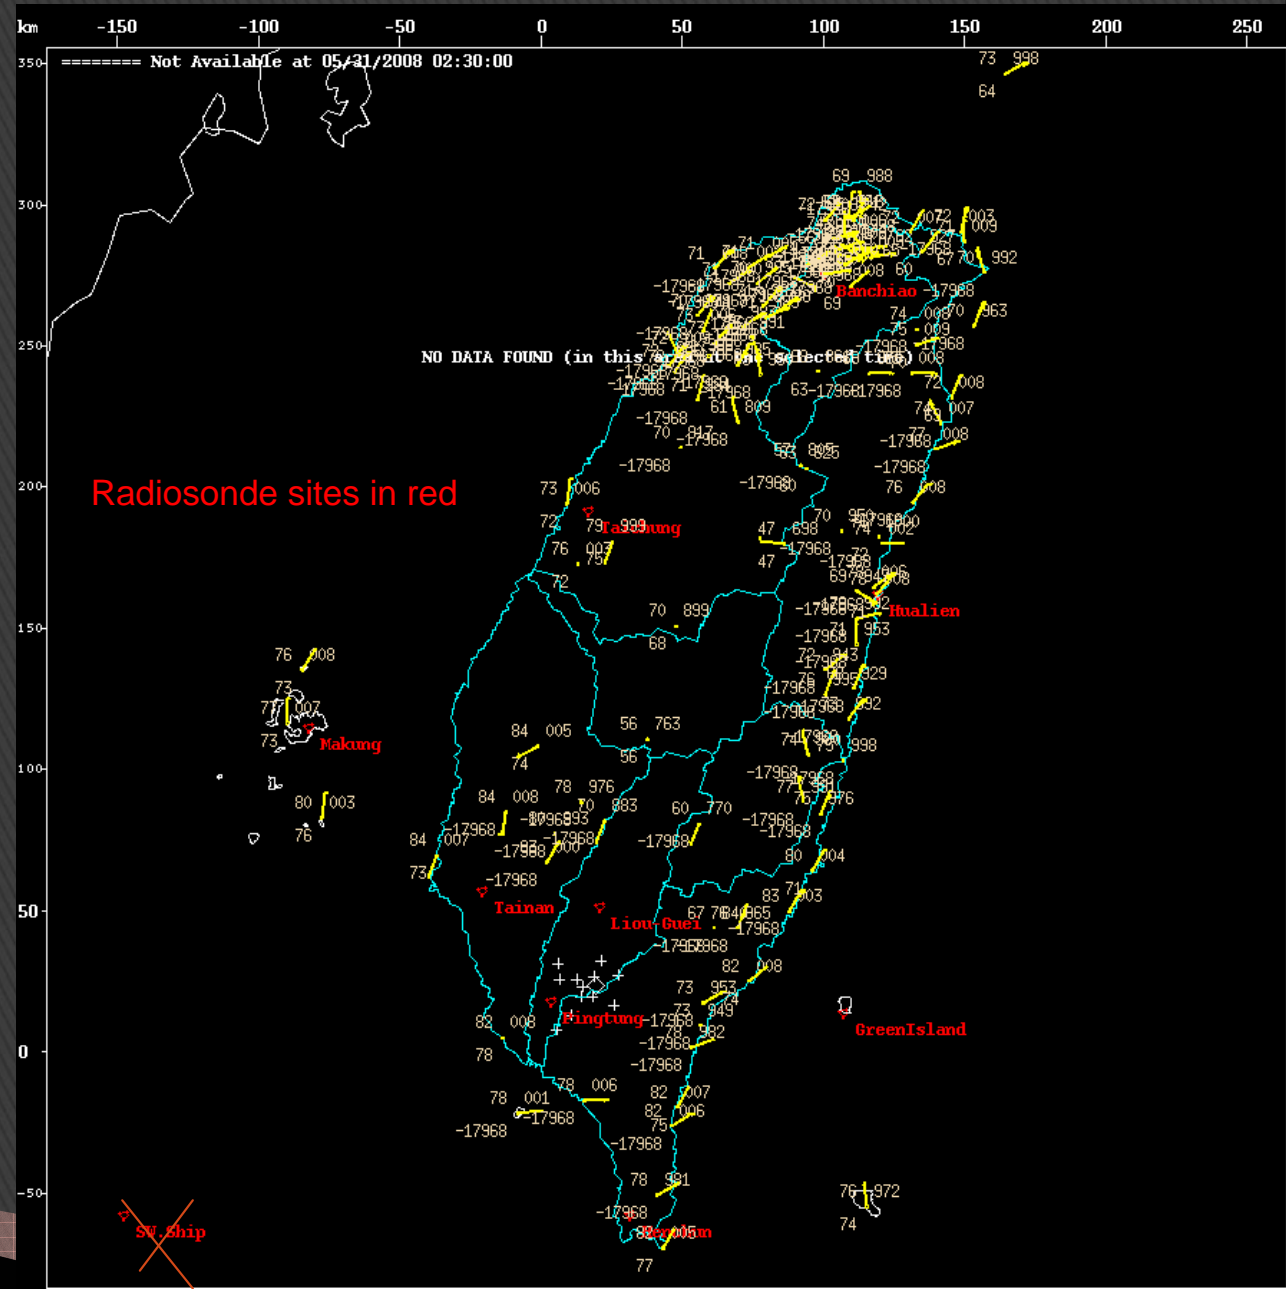

Surface Station and Sounding Data

100+ Surface Stations

- Temperature QC done by John Braun at UCAR/COSMIC

9 of 12 Sounding locations

- Humidity-corrected, (V3) done by Ciesielski et al.
- launches every 3 to 6 hr depending on sounding site

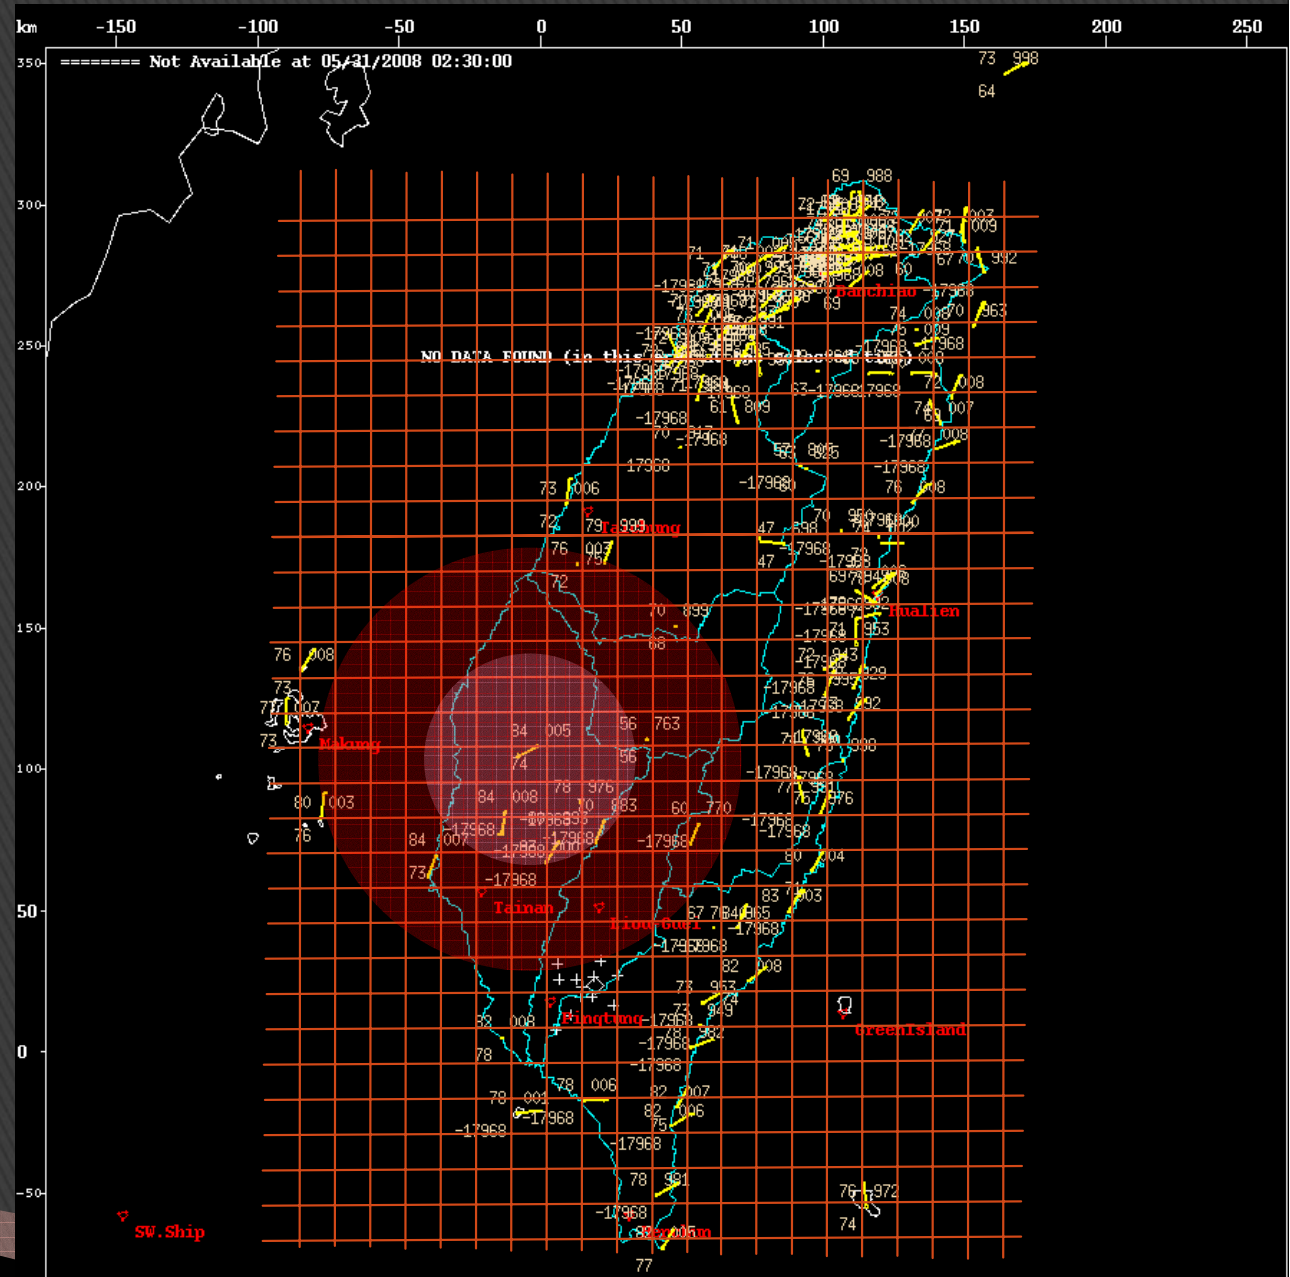

Algorithmic Processing to Retrieve gridded Surface-Based CAPE and CIN fields

MetarCAPECIN algorithm
SurfInterp algorithm

Data is interpolated to a grid using Cressman weighting and Barnes analysis methodologies.

75 km radius specified to grab closest and most recent surface station data

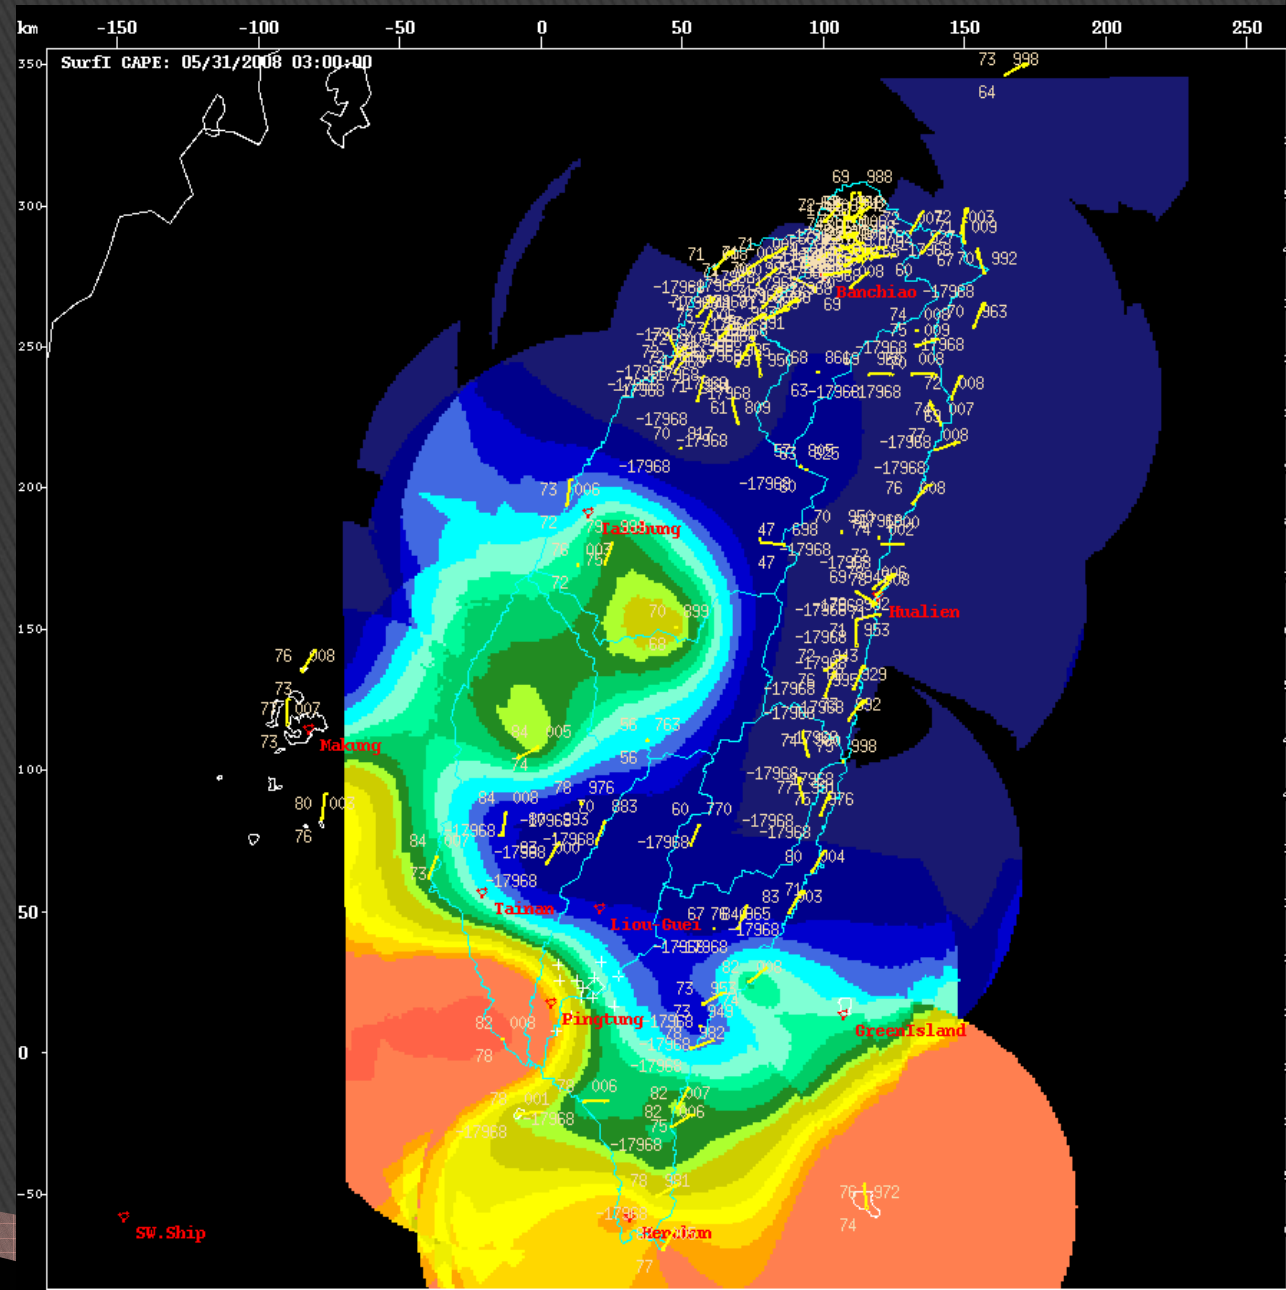

150 km radius specified to grab closest and most recent sounding information

Gridded CAPE field

The CAPE and CIN values are originally calculated from the soundings using the mean T and T_d values in the lowest 100 mb.

Sounding profiles are then modified using the hourly updated surface station T and T_d values to get a new CAPE and CIN value at each grid point

Cases

- ▶ 31 May – Mei Yu frontal– and locally–driven convection
- ▶ 8 June – locally–driven convection
- ▶ 9 June – locally–driven convection, but with an approaching upper level, short wave disturbance

Predictability For Dissipation of Convection

IMPRESSIONS

- ▶ Plan to use 1 min surface station data posted on SOWMEX/TiMREX web site to evaluate CAPE and CIN fields under rapidly evolving situations.
- ▶ Need good QC of the surface data
 - T_d is not recorded at all stations and it is “missing” from stations that do measure this field
 - Braun has noted that there are a large number of temperature “outlier “ values that got thrown out in the QC processing
 - Although wind measurements were not used in this study, we noticed that these measurements seem to fluctuate frequently and specific problematic stations need to be flagged
- ▶ Highly desirable to have as many surface stations located on the western Plains as possible for short-term nowcasting applications.
- ▶ Although we used the V3 sounding data set, there were still a couple of problematic soundings in the data set. We need to modify our algorithm to make better use of the QC flags provided in the data files.

Implications for Nowcasting

- ▶ Taiwan atmosphere generally has high instability as evident from an abundance of CAPE and very little CIN.
- ▶ With plenty of available surface moisture, reaching convective temperature (CT) is likely a large contributor to the timing of convection, as evident in the high correlation between maximum CAPE, maximum surface temperature and initiation of storms along the foothills of the terrain, for the two non-synoptic days examined.
- ▶ In contrast to the U.S. where tracking the decrease in CIN is a useful field in the prediction storm initiation, in Taiwan the CIN field may not likely be a robust identifier for the onset of new convection (except perhaps on more stable days with capping inversions).

Implications for Nowcasting

- ▶ For nowcasting purposes, these CAPE/CIN fields are likely to be most useful in defining more specific areas for the likelihood of new storm development on non-synoptically -driven days, when the NWP models struggle to forecast the exact locations for precipitation (as seen on 8 June).
- ▶ Under synoptic situations, these fields may also be useful in predicting whether convection will be sustained or will dissipate as it moves onshore from ocean -to-land or as it moves over the higher terrain.

Ongoing Efforts

- ▶ Evaluate several of the TiMREX cases events to assess the utility of the CAPE/CIN fields from NWP, VDRAS and observational datasets for short-term nowcasting applications under synoptic and non-synoptic situations.
- ▶ These fields will be evaluated in conjunction with other feature detection “interest” fields in order to produce localized nowcasts of heavy precipitation for the Taiwan townships.
